

## Multiple devices connected to the core switch

### Overview

Switch Overload: Can You Have Too Many Switches in a Network?

One crucial component of any network is the switch, which enables devices to communicate with.

### Key Takeaways

Core switches primarily connect distribution switches, which in turn link to access switches and end-user devices, forming the backbone of a hierarchical network. Role of a Core Switch

A core switch is a high-capacity, high-performance Layer 3 switch positioned at the backbone of an enterprise network. It aggregates traffic from multiple distribution switches and ensures ultra-low latency and maximum throughput across the network. Unlike access switches, core switches are not directly designed for connecting end-user devices but serve as the central hub for routing and switching large volumes of data.

Typical Devices Connected

- **Distribution Switches:** These are the primary devices connected to the core switch. Distribution switches aggregate traffic from access switches and enforce policies such as VLAN routing, QoS, and ACLs.

- **Servers and Data Center Equipment:** High-performance servers, storage arrays, and virtualization hosts may connect directly to the core switch to ensure minimal latency and high-speed data transfer .
  - **Redundant Core Switches:** In high-availability setups, core switches are often paired with another core switch using protocols like VRRP or HSRP for redundancy .
  - **Network Appliances:** Firewalls, load balancers, and WAN routers may also connect to the core layer to facilitate traffic management and security.
- Indirectly Connected Devices

End-user devices such as PCs, VoIP phones, Wi-Fi access points, and IoT devices typically connect to access switches, which then connect to distribution switches, and finally to the core switch . This hierarchical design ensures scalability, fault isolation, and efficient traffic management.

### Identifying Connected Devices

To determine which devices are connected to a core switch, network administrators can use tools such as:

- **SwitchInspector:** Maps switch ports and shows connected devices without physically tracing cables .
- **Cisco Network Assistant:** Provides a graphical interface to view devices connected to each port on Cisco switches .
- **SolarWinds Switch Port Mapper:** Audits and visualizes network connections for large-scale environments .

### Summary

Devices directly connected to a core switch are primarily distribution switches, servers, and network appliances, while end-user devices connect indirectly through access and distribution layers. Using network management tools allows administrators to map and monitor these connections efficiently, ensuring optimal performance and reliability of the network backbone .
