

Optical modulators belong to external modulation

Overview

An optical modulator is a device which is used to modulate a beam of light. The beam may be carried over free space, or propagated through an optical waveguide (optical fibre). Depending on the parameter of a light beam which is manipulated, modulators may be categorized into amplitude modulators, phase modulators, polarization modulators, etc. The easiest way to obtain modulation of intensity of a light beam is to modulate the current driving the light source, e.g. a laser diode.

Key Takeaways

Optical modulators are devices used in external modulation, where a separate modulator alters the light signal rather than modulating the light source directly. Understanding External Modulation

External modulation involves using a separate optical modulator to modify the characteristics of a light wave emitted by a laser or LED, instead of directly varying the light source itself. This approach is particularly important in high-speed optical communication systems, where direct modulation can cause undesirable effects such as chirping, which broadens the laser linewidth and limits data transmission rates.

Role of Optical Modulators

Optical modulators function as electrically controlled devices that adjust the amplitude, phase, or polarization of the light passing through them. They can be classified based on the physical mechanism used:

- Electro-optic modulators: Change the refractive index of a material in response to an electric field, affecting the phase of light .
- Acousto-optic modulators: Use sound waves to diffract and modulate light.
- Magneto-optic modulators: Alter light properties using magnetic fields.
- Electro-absorptive modulators: Vary the absorption coefficient of the material to modulate light intensity .

Advantages of External Modulation

- High-speed operation: Suitable for data rates above 10 Gbps, unlike direct modulation which is limited at lower speeds .
- Reduced chirp: Maintains narrow linewidths for long-distance fiber-optic transmission.
- Flexibility: Can modulate amplitude, phase, or polarization independently of the light source.

Typical Implementation

A common example is the Mach-Zehnder interferometer modulator, often made from lithium niobate (LiNbO_3), which splits the light into two paths, applies a phase shift via an electric field, and recombines the beams to produce amplitude modulation . The modulator acts like an electrically activated shutter, controlling the light output according to the input electrical signal. In summary, optical modulators are integral to external modulation, enabling precise, high-speed control of light signals in modern optical communication systems, and are distinct from direct modulation where the light source itself is modulated .
